

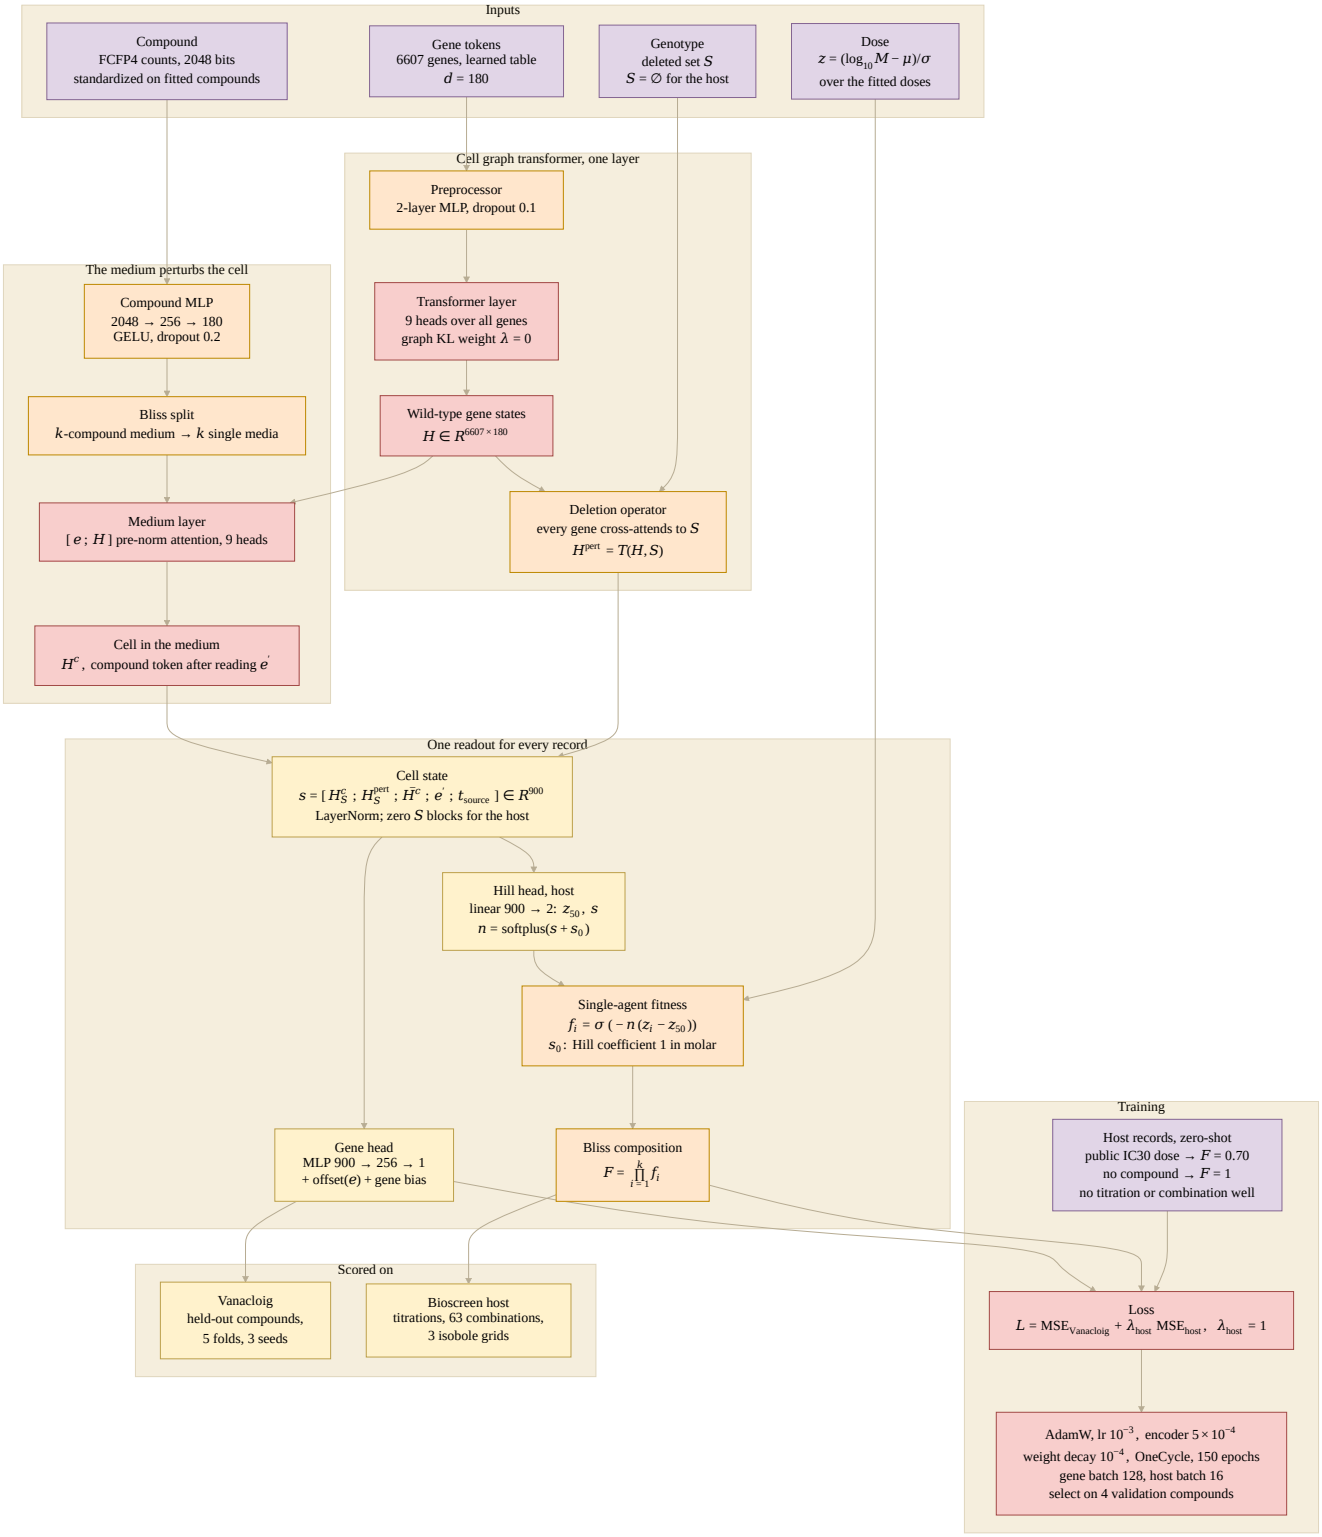

Figure 14: Supplement nine: the leading round-eleven arm, wired. The zero-shot Hill and Bliss arm of fig. 13. Purple, inputs and the host records; orange, the operators (the deletion operator, the compound MLP, the Bliss split, the Hill curve and its composition); red, the transformer layers and the optimization; yellow, the readouts. Every record is a cell: a published strain is read at its deleted genes, and the host is the record with no deleted gene, whose two gene blocks of the cell state are zero. The host's fitness is a Hill curve per inhibitor, its IC50 and slope read from the same cell state the gene head reads, evaluated at the medium's dose and multiplied over the inhibitors of a mixture; the only host records are the published IC30 anchors and the compound-free medium. The graph-prior weight is zero, so the nine gene graphs carry no signal into this arm.
