

shaded band = middle 80% (10th-90th percentile) of the y-axis model's own output; a narrow band means the model returns nearly the same value for every gene.

Panel c quadrants are cut at each model's rank-matched high threshold; counts are TRUE HIGH producers (blue) with the quadrant's all-gene total in parentheses. Rings = the 49 of 100 true highs found by at least one method (FCL 29, CGT 29, shared 9). Color is the FCL paper's RELEASED class label; x is our copy of the Cachera screen. They agree at Spearman 0.73 (88% of attainable) and 18.8% of genes fall in a different bin, which is why the colors overlap along x -- see Fig 7.
